Active Education
Physical Education, Physical Activity and Academic Performance

In schools across the United States, physical education has been substantially reduced—and in some cases completely eliminated—in response to budget concerns and pressures to improve academic test scores. Yet the available evidence shows that children who are physically active and fit tend to perform better in the classroom and that daily physical education does not adversely affect academic performance. Schools can provide outstanding learning environments while improving children’s health through physical education.

**Schools and Physical Activity**

Today, obesity is one of the most pressing health concerns for children. Nearly one-third of children and teens, more than 23 million kids, are overweight or obese—and physical inactivity is a leading contributor to the epidemic. The Surgeon General recommends children should engage in 60 minutes of moderate activity most days of the week, yet estimates show that only 3.8 percent of elementary schools provide daily physical education (PE).

Schools serve as an excellent venue to provide students with the opportunity for daily physical activity, to teach the importance of regular physical activity for health, and to build skills that support active lifestyles. Unfortunately, most children get little to no regular physical activity while in school.

Budgetary constraints and increasing pressure to improve standardized test scores have caused school officials to question the value of PE and other physical activity programs. This has led to a substantial reduction in the time available for PE, and in some cases, school-based physical activity programs have been completely eliminated.

Yet advocates for school-based physical activity programs argue that allocating time for daily PE does not adversely impact academic performance, and that regular exercise may improve students’ concentration and cognitive functioning.
Key Research Results

Sacrificing physical education for classroom time does not improve academic performance

This summary of peer-reviewed research on the relationship between physical activity and academic performance among children and adolescents yields the following insights:

Many school systems have downsized or eliminated PE under the assumption that more classroom time will improve academic performance and increase standardized test scores. The available evidence from several controlled experimental studies in the United States, Canada, and Australia contradicts this view. All of these studies evaluated how additional instructional time for PE impacts academic performance, and clearly demonstrate that physical activity need not be sacrificed for academic excellence.

- In 2007, 287 fourth- and fifth-grade students in British Columbia were evaluated to determine if introducing daily classroom physical activity sessions affected their academic performance. Students in the intervention group participated in daily 10-minute classroom activity sessions in addition to having 80 minutes of PE per week. Despite increasing in-school physical activity time by approximately 50 minutes per week, students receiving the extra physical activity time had similar standardized test scores for mathematics, reading and language arts as did students in the control group.

- In 1999, researchers analyzed data from 759 fourth- and fifth-grade students in California and found that students’ scores on standardized achievement tests were not adversely affected by an intensive PE program that doubled or tripled PE time. On several test scores, students who spent more time in PE performed better than students in control groups.

Within the United States, results from a national longitudinal study and observational data from two studies that compared test scores of children who were exposed to different amounts of PE instructional time have shown that more time in PE does not adversely affect academic performance.

- Girls who were enrolled in PE for 70 or more minutes per week had significantly higher achievement scores in mathematics and reading than did girls who were enrolled in PE for 35 or fewer minutes per week, according to the National Early Childhood Longitudinal Study. Researchers analyzed a nationally representative sample of more than 5,000 students from the 1998–99 kindergarten class as they progressed through grade 5. Among boys, greater exposure to PE was neither positively or negatively associated with academic achievement.

- A study of more than 200 sixth-grade students in Michigan, conducted in 2006, found that students enrolled in PE had similar grades and standardized test scores as students who were not enrolled in PE, despite receiving 55 fewer minutes of daily classroom instruction.

- A study of 311 fourth-grade students in southeastern Massachusetts found that students who received 56 or more hours of PE per school year scored significantly higher on standardized test scores in English and language arts than did students who received 28 hours of PE per school year. The study, which was conducted in 2000–01, found no significant differences on standardized mathematics test scores.
Fourteen published studies analyzing data from approximately 58,000 students between 1967 and 2006 have investigated the link between overall participation in physical activity and academic performance. Eleven of those studies found regular participation in physical activity is associated with improved academic performance.

Eight health surveys involving population-representative samples of children and adolescents from the United States, United Kingdom, Hong Kong and Australia observed statistically significant, positive correlations between physical activity participation and academic performance. However, none of these studies assessed academic performance with standardized educational tests.

One of the studies, conducted in the United States in 2006, analyzed national data collected from nearly 12,000 adolescents to examine the relationship between physical activity and academic performance. Adolescents who reported either participating in school-based physical activities, such as PE and team sports, or playing sports with their parents were 20 percent more likely than their sedentary peers to earn an “A” in math or English.

Three other smaller studies conducted between 1970 and 2006 involving students from one or two schools also reported a positive correlation between physical activity and academic performance.

Two studies found no evidence of a relationship, positive or negative, between physical activity and academic performance, and one study conducted in Canada in 2000 reported a trivial negative association between physical activity and standardized test scores.

Evidence supporting the association between physical activity and enhanced academic performance is strengthened by findings that link higher levels of physical fitness with improved academic performance among children and teens. Two national studies, in Australia and South Korea, along with four studies conducted in the United States, found physical fitness scores to be significantly and positively associated with academic performance. These studies included students from elementary school through high school.

Researchers analyzed FITNESSGRAM® test results from more than 2.4 million Texas students in grades 3 to 12 during the 2007–08 school year and found significant school-level correlations between physical fitness achievement and better performance on state standardized tests. Higher physical fitness achievement also was associated with better school attendance rates and fewer disciplinary incidents involving drugs, alcohol, violence or truancy. Associations were stronger for cardiovascular fitness than for measures of body mass index (BMI), but the patterns were consistent. The analyses controlled for potential confounding variables, such as socioeconomic status, minority status and school size, that could influence the correlations. The study is currently in review, and as of August 2009, these data were unpublished.
A cross-sectional study of 2004–05 data from 1,800 Massachusetts middle-school students found that students who passed more fitness tests during physical education performed better on achievement tests in math and English than did students who had poorer fitness test results.44

According to a 2007 study of 259 third- and fifth-grade students, children who performed better on aerobic capacity fitness tests were more likely to score higher on state math and reading exams.46
Activity breaks can improve cognitive performance and classroom behavior

According to seven studies involving elementary-school students, and one survey of elementary- and middle-school administrators, regular physical activity breaks during the school day may enhance academic performance, academic focus and/or behavior in the classroom. It is important to note that cognitive and behavioral responses to physical activity breaks during the school day have not been systematically investigated among middle- or high-school students.

- Teachers reported better classroom behavior for students who had more than 15 minutes of daily recess, according to an analysis of 1998–99 data for approximately 11,000 students ages 8 to 9. Thirty percent of students in the study had little or no daily recess. Further analysis showed that only 7 percent to 14 percent of black, Hispanic and low-income students had daily recess, compared with 54 percent to 67 percent of white and affluent students.

- A 2008 survey of representatives from 106 North Carolina school districts found that improved academic focus among students was the most widely cited benefit of a statewide policy mandating at least 30 minutes of daily physical activity for students in kindergarten through grade 8. Improvement in students’ focus was reported by 27 percent of elementary-school officials and 15 percent of middle-school officials.

- Other results from the survey showed increased student alertness (reported by 17% of elementary- and middle-school officials) and improved student behavior (reported by 12% of elementary-school officials and 8% of middle-school officials).

- In 1998, researchers in Georgia studied the effects of an activity break on classroom behavior in a sample of 43 fourth-grade students. Students exhibited significantly more on-task classroom behavior and significantly less fidgeting on days with a scheduled activity break than on days without one.

- A 12-week research project conducted in North Carolina in 2006 evaluated the effects of providing elementary-school students with a daily 10-minute activity break. Among 243 students in kindergarten through grade 4, a break without physical activity decreased on-task behavior, but a daily physical activity break increased on-task behavior significantly — by an average of 8 percent. Among the least on-task students, activity breaks improved on-task behavior by 20 percent.

- In a study conducted in 1999 with 177 New Jersey elementary-school students, researchers compared scores on a concentration test after students completed either a classroom lesson or a 15-minute physical activity session. Fourth-grade students exhibited significantly better concentration scores after completing the physical activity. Among second- and third-grade students, the physical activity intervention was neither beneficial nor detrimental to test performance.
Conclusion

- Studies consistently show that more time in physical education and other school-based physical activity does not adversely affect academic performance.
- In some cases, more time in physical education leads to improved grades and standardized test scores.
- Physically active and fit children tend to have better academic achievement.
- Evidence links higher levels of physical fitness with better school attendance and fewer disciplinary problems.
- There are several possible mechanisms by which physical education and regular physical activity could improve academic achievement, including enhanced concentration skills and classroom behavior.
- Additional research is needed to determine the impact of physical activity on academic performance among those children who are at highest risk for obesity in the United States, including black, Latino, American Indian and Alaska Native, and Asian-American and Pacific Islander children, as well as children living in lower-income communities.
